We'll dive deep into the core concepts, tackle common problem types, and equip you with the tools to conquer even the trickiest fluid dynamics challenges. So, grab your metaphorical beaker and let's get started on this fluid journey!

Understanding the Fundamentals: What Exactly Are Fluids?

Before we can solve problems, we need a solid grasp of what we're dealing with. In physics, a fluid is any substance that can flow and takes the shape of its container. This includes both liquids (like water, oil, and honey) and gases (like air, helium, and steam). Unlike solids, fluids don't have a fixed shape; their molecules are free to move past one another. Key properties of fluids that are crucial for solving problems include:

1. **Density (ρ):** This is the mass of a fluid per unit volume. Denser fluids sink in less dense fluids (think oil and water).
2. **Viscosity (μ):** This measures a fluid's resistance to flow. Honey is highly viscous, while water has low viscosity.
3. **Pressure (P):** This is the force exerted by a fluid per unit area. It's a fundamental concept in hydrostatic and fluid mechanics problems.
4. **Buoyancy:** The upward force exerted by a fluid that opposes the weight of an immersed object.

Hydrostatics: The Physics of Stationary Fluids

Hydrostatics deals with fluids at rest. This might seem simple, but it leads to some incredibly important principles.

Pressure in Fluids: It's Not Just About Depth!

One of the most fundamental concepts in hydrostatics is pressure. You've probably experienced this when diving deep into a swimming pool – the pressure increases with depth. The formula for hydrostatic pressure is: $P = \rho gh$ Where:

1. P is the pressure
2. ρ is the fluid density
3. g is the acceleration due to gravity
4. h is the depth of the fluid

This equation tells us that pressure depends on the density of the fluid, gravity, and how deep you are. It's important to note that pressure in a static fluid acts equally in all directions. **Problem Type 1: Calculating Pressure at a Specific Depth** Let's say you're working on an oil rig and need to know the pressure at the bottom of a well that's 1000 meters deep. The density of the oil is 850 kg/m^3 . **Solution:** We can directly apply the hydrostatic pressure formula: $P = \rho gh$ $P = (850 \text{ kg/m}^3) \times (9.81 \text{ m/s}^2) \times (1000 \text{ m})$ $P \approx 8.34 \times 10^6 \text{ Pa}$ So, the pressure at the bottom of the well is approximately 8.34 million Pascals! This is a significant pressure, highlighting the importance of robust engineering in such environments.

Archimedes' Principle: The Magic of Buoyancy

Archimedes' Principle is the reason why ships float and balloons rise. It states that an object submerged in a fluid experiences an upward buoyant force equal to the weight of the fluid displaced by the object. The buoyant force (F_B) is calculated as: $F_B = \rho_{\text{fluid}} V_{\text{submerged}} g$ Where:

1. ρ_{fluid} is the density of the fluid
2. $V_{\text{submerged}}$ is the volume of the object submerged in the fluid
3. g is the acceleration due to gravity

An object floats if the buoyant force is equal to its weight. It sinks if its weight is greater than the buoyant force, and it rises if the buoyant force is greater than its weight.

Problem Type 2: Determining if an Object Will Float or Sink Imagine you have a block of wood with a volume of 0.1 m^3 and a mass of 60 kg . You place it in water (density 1000 kg/m^3). Will it float? **Solution:** First, calculate the weight of the wood: Weight (W) = mass (m) $\times$ gravity (g) $W = 60 \text{ kg} \times 9.81 \text{ m/s}^2 \approx 588.6 \text{ N}$ Next, we need to determine the buoyant force. Since the wood will partially sink, the submerged volume will be less than its total volume. However, if it floats, the buoyant force will equal its weight. Let's assume it floats and see if the density of the wood is less than water. Density of wood (ρ_{wood}) = mass / volume $\rho_{\text{wood}} = 60 \text{ kg} / 0.1 \text{ m}^3 = 600 \text{ kg/m}^3$ Since the density of the wood (600 kg/m^3) is less than the density of water (1000 kg/m^3), the wood will float. When it floats, the buoyant force will be equal to its weight (588.6 N). The volume of water displaced can be calculated by setting the buoyant force equal to its weight and solving for $V_{\text{submerged}}$: $588.6 \text{ N} = (1000 \text{ kg/m}^3) \times V_{\text{submerged}} \times (9.81 \text{ m/s}^2)$ $V_{\text{submerged}} \approx 0.06 \text{ m}^3$ So, about 0.06 m^3 of the wood will be submerged.

Hydrodynamics: The Physics of Moving Fluids

Hydrodynamics, or fluid mechanics, deals with fluids in motion. This is where things get a bit more complex, involving concepts like flow rate and energy conservation.

The Principle of Continuity: What Goes In, Must Come Out

The Principle of Continuity is a statement of mass conservation for fluids. It essentially says that for an incompressible fluid (one whose density doesn't change), the volume flow rate must be constant throughout a pipe or channel. The volume flow rate (Q) is given by: $Q = Av$ Where:

1. A is the cross-sectional area of the flow
2. v is the average velocity of the fluid

So, if the area decreases, the velocity must increase to maintain a constant flow rate.

Problem Type 3: Calculating Fluid Velocity in a Constricting Pipe Water flows through a pipe with a radius of 0.1 m. At one point, the pipe narrows to a radius of 0.05 m. If the water velocity in the wider section is 2 m/s, what is the velocity in the narrower section? **Solution:** First, calculate the areas: Area 1 (A_1) = $\pi r_1^2 = \pi (0.1 \text{ m})^2 = 0.01\pi \text{ m}^2$ Area 2 (A_2) = $\pi r_2^2 = \pi (0.05 \text{ m})^2 = 0.0025\pi \text{ m}^2$ Now, apply the continuity equation ($A_1 v_1 = A_2 v_2$): $(0.01\pi \text{ m}^2) \times (2 \text{ m/s}) = (0.0025\pi \text{ m}^2) \times v_2$ Solving for v_2 : $v_2 = \frac{(0.01\pi \text{ m}^2) \times (2 \text{ m/s})}{0.0025\pi \text{ m}^2} = 8 \text{ m/s}$ The water velocity increases to 8 m/s in the narrower section. This is why a garden hose sprays water further when you pinch the end!

Bernoulli's Equation: The Symphony of Pressure, Velocity, and Height

Bernoulli's Equation is a cornerstone of fluid dynamics, representing a form of energy conservation for flowing fluids. It relates the pressure, velocity, and height of a fluid at different points along a streamline. For an ideal fluid (incompressible and non-viscous), the equation is: $P + \frac{1}{2} \rho v^2 + \rho gh = \text{constant}$ Where:

1. P is the pressure
2. ρ is the fluid density
3. v is the fluid velocity
4. g is the acceleration due to gravity
5. h is the height above a reference point

This equation tells us that where the velocity of a fluid is high, its pressure is low, and vice versa. It also accounts for changes in potential energy due to height. **Problem**

Type 4: Applying Bernoulli's Principle to a Venturi Meter A Venturi meter is used to measure flow rate by constricting a pipe. Imagine water flowing through a horizontal pipe. At a wide section (radius 0.04 m), the pressure is 200,000 Pa and the velocity is 1 m/s. At a narrower section (radius 0.02 m), what is the pressure? **Solution:** First, calculate the areas and velocity in the narrower section using the continuity equation as we did before. $A_1 = \pi (0.04 \text{ m})^2 = 0.0016\pi \text{ m}^2$ $A_2 = \pi (0.02 \text{ m})^2 = 0.0004\pi \text{ m}^2$ $A_1 v_1 = A_2 v_2$ $(0.0016\pi \text{ m}^2) \times (1 \text{ m/s}) = (0.0004\pi \text{ m}^2) \times v_2$ $v_2 = 4 \text{ m/s}$ Now, apply Bernoulli's Equation. Since the pipe is horizontal, the height (h) is the same at both points, so ρgh terms cancel out. $P_1 + \frac{1}{2} \rho v_1^2 = P_2 + \frac{1}{2} \rho v_2^2$ $200,000 \text{ Pa} + \frac{1}{2} (1000 \text{ kg/m}^3) (1 \text{ m/s})^2 = P_2 + \frac{1}{2} (1000 \text{ kg/m}^3) (4 \text{ m/s})^2$ $200,000 \text{ Pa} + 500 \text{ Pa} = P_2 + 8000 \text{ Pa}$ $P_2 = 200,000 \text{ Pa} - 8000 \text{ Pa}$ $P_2 = 192,000 \text{ Pa}$ The pressure in the narrower section is 192,000 Pa, which is lower than the pressure in the wider section. This pressure difference can be used to calculate the flow rate.

Dealing with Viscosity: When Things Get Sticky

Real fluids aren't ideal; they have viscosity. Viscosity introduces friction within the fluid and between the fluid and its boundaries, leading to energy losses and a more complex flow behavior.

Viscous Flow and Drag Force

Viscosity plays a crucial role in drag force – the resistance an object experiences when moving through a fluid. For slow-moving objects in a viscous fluid, Stokes' Law describes the drag force: $F_D = 6 \pi \mu r v$ Where:

1. F_D is the drag force
2. μ is the dynamic viscosity of the fluid
3. r is the radius of the object (assuming a sphere)
4. v is the velocity of the object

This formula highlights that drag increases with viscosity, object size, and velocity.

Problem Type 5: Calculating Terminal Velocity A small spherical raindrop with a radius of 1 mm falls through the air. The viscosity of air is approximately 1.8×10^{-5} Pa·s, and its density is about 1.2 kg/m^3 . The density of water is 1000 kg/m^3 . What is its terminal velocity? **Solution:** Terminal velocity is reached when the drag force equals the gravitational force (weight) of the object. Weight of raindrop (W) = $mg = (\rho_{\text{water}} \times V) \times g = (\rho_{\text{water}} \times \frac{4}{3}\pi r^3) \times g$
 $W = (1000 \text{ kg/m}^3) \times (\frac{4}{3}\pi (1 \times 10^{-3} \text{ m})^3) \times (9.81 \text{ m/s}^2) \approx 4.12 \times 10^{-5} \text{ N}$ Drag force (F_D) = $6 \pi \mu r v_t$
 $F_D = 6 \pi (1.8 \times 10^{-5} \text{ Pa·s}) (1 \times 10^{-3} \text{ m}) v_t \approx 3.39 \times 10^{-7} v_t$ At terminal velocity (v_t), $W = F_D$: $4.12 \times 10^{-5} \text{ N} = 3.39 \times 10^{-7} v_t$
 $v_t = \frac{4.12 \times 10^{-5} \text{ N}}{3.39 \times 10^{-7}} \approx 121.5 \text{ m/s}$
This seems quite high for a raindrop! This calculation uses Stokes' Law, which is valid for *low Reynolds numbers* (slow, viscous flow). For a raindrop, the flow is more turbulent, and a different drag force formula would be needed, resulting in a much lower terminal velocity (around 9 m/s). This illustrates the importance of understanding the flow regime.

Unlocking the Secrets of Fluid Dynamics: Common Physics Problems and Their Solutions

The world around us is awash in fluid phenomena. From the gentle ripple of a pond to the powerful roar of a jet engine, the behavior of liquids and gases dictates much of our daily experience. Understanding **fluids physics**, also known as **fluid mechanics**, is not just an academic pursuit; it's crucial for engineers designing aircraft, medical professionals developing prosthetics, environmental scientists studying ocean currents, and even home cooks perfecting their soufflés. However, the inherent complexity of fluid motion often presents challenging **fluid dynamics problems**. This article delves into some of the most common types of these problems, exploring the underlying physics and the systematic approaches to finding their solutions.

Fluid mechanics is broadly divided into three branches: **statics**, dealing with fluids at rest; **kinematics**, focusing on the motion of fluids without considering the forces that cause it; and **dynamics**, which examines the relationship between fluid motion and the forces acting upon it. Many real-world applications involve intricate interactions and often require advanced mathematical tools, but grasping fundamental principles is the cornerstone of mastering this fascinating field. We'll cover essential concepts like pressure, buoyancy, flow rate, viscosity, and the governing equations that help us predict fluid behavior.

The Foundations: Pressure and Buoyancy

One of the most fundamental concepts in fluid physics is **pressure**. Defined as force per unit area, pressure within a fluid at rest increases with depth due to the weight of the fluid above. This principle is elegantly demonstrated in Archimedes' principle and the concept of **buoyancy**. Archimedes' principle states that a body immersed in a fluid experiences an upward buoyant force equal to the weight of the fluid displaced by the body. This explains why ships float and hot air balloons rise.

Problem Type 1: Calculating Pressure and Force in Fluids

A common problem involves calculating the pressure at a certain depth in a liquid and

the resultant force on a submerged surface. For a liquid of uniform density ρ at rest, the gauge pressure P_g at a depth h is given by:

$$P_g = \rho g h$$

where g is the acceleration due to gravity. The absolute pressure P_{abs} is the sum of the gauge pressure and the atmospheric pressure (P_{atm}):

$$P_{abs} = P_{atm} + \rho g h$$

Solution Approach: To solve such problems, identify the given density of the fluid, the depth of interest, and the atmospheric pressure if absolute pressure is required. Ensure consistent units are used. For forces on submerged surfaces, especially those not horizontal, integration is often necessary to sum the pressure forces acting over the varying depth.

Example Scenario: Consider a cylindrical tank filled with water ($\rho_{water} \approx 1000 \text{ kg/m}^3$) to a depth of 2 meters. What is the pressure at the bottom of the tank, assuming atmospheric pressure is $101,325 \text{ Pa}$? What is the force on the circular base of the tank (radius 0.5 m)?

Solution:

Gauge pressure at the bottom: $P_g = (1000 \text{ kg/m}^3)(9.81 \text{ m/s}^2)(2 \text{ m}) = 19,620 \text{ Pa}$.

Absolute pressure at the bottom: $P_{abs} = 101,325 \text{ Pa} + 19,620 \text{ Pa} = 120,945 \text{ Pa}$.

The force on the circular base is $F = P_{abs} \times A$, where A is the area of the base.

Area $A = \pi r^2 = \pi (0.5 \text{ m})^2 = 0.25\pi \text{ m}^2 \approx 0.785 \text{ m}^2$.

Force $F = 120,945 \text{ Pa} \times 0.785 \text{ m}^2 \approx 95,042 \text{ N}$.

Problem Type 2: Buoyancy and Floating Objects

Buoyancy problems typically involve determining whether an object will float, sink, or remain neutrally buoyant, and calculating the submerged volume if it floats.

Solution Approach: An object floats if the buoyant force equals its weight. The buoyant force (F_B) is given by:

$$F_B = \rho_{fluid} g V_{submerged}$$

where $V_{submerged}$ is the volume of the object submerged in the fluid. The weight of the object (W) is:

$$W = m_{object} g = \rho_{object} g V_{object}$$

For floating, $F_B = W$, so $\rho_{\text{fluid}} g V_{\text{submerged}} = \rho_{\text{object}} g V_{\text{object}}$. This simplifies to:

$$\frac{V_{\text{submerged}}}{V_{\text{object}}} = \frac{\rho_{\text{object}}}{\rho_{\text{fluid}}}$$

Example Scenario: A solid block of wood with a density of 600 kg/m^3 and a volume of 0.01 m^3 is placed in water ($\rho_{\text{water}} = 1000 \text{ kg/m}^3$). Will it float? If so, what fraction of its volume will be submerged?

Solution: Since $\rho_{\text{object}} < \rho_{\text{fluid}}$ ($600 < 1000$), the wood will float. The fraction of submerged volume is:

$$\frac{V_{\text{submerged}}}{V_{\text{object}}} = \frac{600 \text{ kg/m}^3}{1000 \text{ kg/m}^3} = 0.6$$

Therefore, 60% of the wood's volume will be submerged.

Fluid Motion: Flow Rate and the Continuity Equation

When fluids are in motion, we often analyze their **flow rate**, which describes how much fluid passes a point per unit time. This is closely linked to the **continuity equation**, a fundamental principle derived from the conservation of mass. For an incompressible fluid (density remains constant), the continuity equation states that the mass flow rate is constant throughout a pipe or channel, even if the cross-sectional area changes.

Problem Type 3: Applying the Continuity Equation

This type of problem involves relating the velocity and cross-sectional area of a fluid flow at different points.

Solution Approach: The volumetric flow rate (Q) is given by:

$$Q = A v$$

where A is the cross-sectional area and v is the average flow velocity. For a continuous flow, the volumetric flow rate at point 1 equals the volumetric flow rate at point 2:

$$A_1 v_1 = A_2 v_2$$

This equation is crucial for understanding why a hose's water stream speeds up when you narrow its opening.

Example Scenario: Water flows through a pipe. At section 1, the pipe has a diameter of 10 cm and the water flows at 2 m/s. At section 2, the pipe narrows to a diameter of 5 cm. What is the velocity of the water at section 2?

Solution:

$$\text{Area 1: } A_1 = \pi (d_1/2)^2 = \pi (0.1 \text{ m}/2)^2 = \pi (0.05 \text{ m})^2 =$$

$$0.0025\pi \, \text{m}^2.$$

$$\text{Area 2: } A_2 = \pi (d_2/2)^2 = \pi (0.05 \, \text{m}/2)^2 = \pi (0.025 \, \text{m})^2 = 0.000625\pi \, \text{m}^2.$$

Using the continuity equation, $A_1 v_1 = A_2 v_2$:

$$(0.0025\pi \, \text{m}^2)(2 \, \text{m/s}) = (0.000625\pi \, \text{m}^2) v_2$$

$$v_2 = \frac{(0.0025\pi \, \text{m}^2)(2 \, \text{m/s})}{0.000625\pi \, \text{m}^2} = 8 \, \text{m/s}$$

The water velocity increases to 8 m/s in the narrower section.

The Dynamics of Fluid Flow: Bernoulli's Principle and Viscosity

As fluids move, their speed, pressure, and elevation are interconnected. **Bernoulli's principle**, derived from the conservation of energy for inviscid, incompressible flow, quantifies this relationship. It states that the sum of the static pressure, dynamic pressure (related to velocity), and potential energy per unit volume is constant along a streamline.

On the other hand, many real-world fluid flows are not inviscid. **Viscosity** is a measure of a fluid's resistance to flow. It's the internal friction within the fluid. Understanding viscosity is critical for analyzing phenomena like fluid friction, drag, and pumping power requirements.

Problem Type 4: Applying Bernoulli's Equation

Bernoulli's equation is powerful for analyzing pressure changes due to velocity changes in fluid flow, provided certain assumptions (incompressibility, inviscid flow, steady flow, along a streamline) are met.

The equation is:

$$P_1 + \frac{1}{2} \rho v_1^2 + \rho g h_1 = P_2 + \frac{1}{2} \rho v_2^2 + \rho g h_2$$

where P is static pressure, $\frac{1}{2} \rho v^2$ is dynamic pressure, and $\rho g h$ is hydrostatic pressure.

Solution Approach: Identify two points along a streamline. List the known variables (pressure, velocity, height) at each point. Apply Bernoulli's equation, simplifying based on what is constant or negligible (e.g., if the pipe is horizontal, $h_1 = h_2$). Solve for the unknown variable.

Example Scenario: Air (density $\approx 1.2 \, \text{kg/m}^3$) flows horizontally through a pipe. At point 1, the velocity is 10 m/s and the pressure is 100,000 Pa. At point 2, where the pipe has narrowed, the velocity is 20 m/s. Assuming

the flow is horizontal ($h_1 = h_2$), what is the pressure at point 2?

Solution:

From Bernoulli's equation, with $h_1 = h_2$ and ρ constant:

$$P_1 + \frac{1}{2} \rho v_1^2 = P_2 + \frac{1}{2} \rho v_2^2$$

$$P_2 = P_1 + \frac{1}{2} \rho (v_1^2 - v_2^2)$$

$$P_2 = 100,000 \text{ Pa} + \frac{1}{2} (1.2 \text{ kg/m}^3) ((10 \text{ m/s})^2 - (20 \text{ m/s})^2)$$

$$P_2 = 100,000 \text{ Pa} + 0.6 \text{ kg/m}^3 (100 \text{ m}^2/\text{s}^2 - 400 \text{ m}^2/\text{s}^2)$$

$$P_2 = 100,000 \text{ Pa} + 0.6 \text{ kg/m}^3 (-300 \text{ m}^2/\text{s}^2)$$

$$P_2 = 100,000 \text{ Pa} - 180 \text{ Pa} = 99,820 \text{ Pa}$$

The pressure decreases as the velocity increases.

Problem Type 5: Viscous Flow and Poiseuille's Law

For steady, laminar flow of a viscous, incompressible fluid through a cylindrical pipe of constant cross-section, **Poiseuille's Law** (or the Hagen-Poiseuille equation) relates the pressure drop (ΔP) to the flow rate (Q):

$$Q = \frac{\pi R^4 \Delta P}{8 \eta L}$$

where R is the pipe radius, ΔP is the pressure difference across the length L , and η is the dynamic viscosity of the fluid.

Solution Approach: This equation is useful for determining pressure drop, flow rate, or viscosity given the other parameters. It highlights the strong dependence of flow rate on pipe radius (R^4) and pressure drop, and its inverse dependence on viscosity and length.

Example Scenario: Oil with a viscosity of $0.01 \text{ Pa} \cdot \text{s}$ flows through a pipe of radius 2 cm and length 10 m. If the pressure drop across the pipe is 5000 Pa, what is the flow rate?

Solution:

Radius $R = 0.02 \text{ m}$.

Length $L = 10 \text{ m}$.

Viscosity $\eta = 0.01 \text{ Pa} \cdot \text{s}$.

Pressure drop $\Delta P = 5000 \text{ Pa}$.

$$Q = \frac{\pi (0.02 \text{ m})^4 (5000 \text{ Pa})}{8 (0.01 \text{ Pa} \cdot \text{s})}$$

$$\text{Pa} \cdot \text{s}) (10 \text{ m})^3$$

$$Q = \frac{\pi (1.6 \times 10^{-7} \text{ m})^4 (5000 \text{ Pa})}{0.8 \text{ Pa} \cdot \text{s} \cdot \text{m}}$$

$$Q \approx \frac{2.513 \times 10^{-3} \text{ m}^4 \cdot \text{Pa}}{0.8 \text{ Pa} \cdot \text{s} \cdot \text{m}} \approx 3.14 \times 10^{-3} \text{ m}^3/\text{s}$$

The flow rate is approximately 0.00314 cubic meters per second.

Navier-Stokes Equations: The Ultimate Challenge

While the above principles address many common problems, the most general and powerful set of equations governing fluid motion are the **Navier-Stokes equations**. These are a system of partial differential equations that describe the motion of viscous fluid substances. They are derived from Newton's second law applied to a fluid element, accounting for viscous forces, pressure gradients, and body forces.

The Navier-Stokes equations are notoriously difficult to solve analytically, except for simplified cases. Many practical fluid mechanics problems require numerical solutions using computational fluid dynamics (CFD). However, understanding their derivation and the physical meaning of their terms is essential for advanced study and for interpreting CFD results.

Questions & Answers About fluids physics problems and solutions

No	Question	Answer
----	----------	--------

1	How does viscosity affect fluid flow, and can you give a practical example?	Viscosity is a fluid's resistance to flow. Higher viscosity means more resistance. For example, honey (high viscosity) flows much slower than water (low viscosity) due to the internal friction between its fluid layers.
2	What is Bernoulli's principle, and how is it applied in everyday life?	Bernoulli's principle states that for an inviscid flow, an increase in the speed of the fluid occurs simultaneously with a decrease in pressure or a decrease in the fluid's potential energy. It's why airplane wings generate lift: faster-moving air over the curved top creates lower pressure, pushing the wing upwards.
3	Can you explain Archimedes' principle and its relevance to buoyancy?	Archimedes' principle states that a body wholly or partially submerged in a fluid is buoyed up by a force equal to the weight of the fluid displaced by the body. This is why ships float: they displace a volume of water whose weight equals the ship's total weight.
4	What's the difference between laminar and turbulent flow, and why does it matter?	Laminar flow is smooth and orderly, with fluid layers sliding past each other. Turbulent flow is chaotic and irregular, with eddies and mixing. It matters because turbulent flow generally involves higher energy loss and is more prone to drag, impacting things like pipe design and aircraft efficiency.
5	How do pressure and depth relate in a static fluid, and what's the formula?	In a static fluid, pressure increases linearly with depth. The formula is $P = \rho gh$, where P is the pressure, ρ (rho) is the fluid density, g is the acceleration due to gravity, and h is the depth. This is why deep-sea submarines need strong hulls.
6	What is surface tension, and what phenomena does it explain?	Surface tension is the tendency of liquid surfaces to shrink into the minimum surface area possible. It's caused by cohesive forces between molecules. It explains why water forms droplets, why insects can walk on water, and how capillary action works.
7	How can we calculate the flow rate of a fluid through a pipe?	The flow rate (Q) is the volume of fluid passing a point per unit time. It can be calculated as $Q = Av$, where A is the cross-sectional area of the pipe and v is the average fluid velocity. For example, a wider pipe with the same velocity will have a higher flow rate.
