Solving Linear Equations

Linear equations are the cornerstone of basic algebra. They involve finding the value of an unknown variable (usually represented by 'x' or 'y') that makes the equation true. The general form of a linear equation is $ax + b = c$, where 'a', 'b', and 'c' are constants.

Example: Solve for x: $3x + 5 = 14$

Solution: 1. **Subtract 5 from both sides:** $3x = 9$ 2. **Divide both sides by 3:** $x = 3$ Let's visualize the process:

Step	Equation	Explanation
1	$3x + 5 = 14$	Original equation
2	$3x = 9$	Subtract 5 from both sides
3	$x = 3$	Divide both sides by 3

Working with Inequalities

Inequalities compare two expressions using symbols like $<$ (less than), $>$ (greater than), $\leq$ (less than or equal to), and $\geq$ (greater than or equal to). Solving inequalities involves similar steps to solving equations, but with one crucial difference: when multiplying or dividing by a negative number, you must reverse the inequality sign. *Example:* Solve for x : $2x - 4 > 6$

Solution: 1. **Add 4 to both sides:** $2x > 10$ 2. **Divide both sides by 2:** $x > 5$ This means x can be any number greater than 5.

Understanding Algebraic Expressions

Algebraic expressions are combinations of variables, constants, and operators ($+$, $-$, $\times$, $\div$). Simplifying algebraic expressions involves combining like terms and applying the order of operations (PEMDAS/BODMAS). *Example:* Simplify $3x + 2y - x + 5y$ **Solution:** Combine like terms: $(3x - x) + (2y + 5y) = 2x + 7y$

Solving Word Problems

Many real-world problems can be translated into algebraic equations. The key is to identify the unknown quantity, assign it a variable, and then write an equation based on the given information. *Example:* John is twice as old as Mary. The sum of their ages is 30. How old is Mary? *Solution:* Let x represent Mary's age. John's age is $2x$. The equation is $x + 2x = 30$. Solving for x gives $x = 10$. Therefore, Mary is 10 years old.

Graphing Linear Equations

Linear equations can be represented graphically as straight lines. The slope and y-intercept of the line provide valuable information about the equation. **Example:** Graph the equation $y = 2x + 1$. This equation has a slope of 2 and a y-intercept of 1. You can plot two points, like (0, 1) and (1, 3), and draw a line through them. **(Insert a simple graph here showing the line $y = 2x + 1$)** This graph visually represents all the points (x, y) that satisfy the equation. *Conclusion:* Mastering basic algebra opens doors to a deeper understanding of mathematics and its numerous applications in various fields. By consistently practicing solving equations, inequalities, and simplifying expressions, you'll build a strong foundation that will serve you well in your future academic and professional endeavors. Remember, practice is key! Work through numerous problems, and don't hesitate to seek help when needed. The effort you put in will be richly rewarded.

Unlocking the Power of Algebra: Essential Problems and Solutions for Beginners

Ever felt a twinge of dread when you hear the word "algebra"? You're not alone! For many, algebra can seem like a daunting maze of letters and symbols. But what if I told you that algebra is actually a powerful tool for problem-solving, applicable to everyday situations, and far more approachable than you might think?

In this comprehensive guide, we're going to demystify basic algebra. We'll tackle common algebra problems, break down the solutions step-by-step, and equip you with the confidence to conquer this fundamental branch of mathematics. So, grab a notepad, settle in, and let's embark on this algebraic journey together!

What Exactly is Basic Algebra?

Before we dive into problems, let's get a clear understanding of what basic algebra is all about. At its core, algebra is a way to represent unknown quantities using symbols, most commonly letters like 'x', 'y', or 'a'. These symbols, called

variables, allow us to express relationships and solve for these unknowns. Think of it as a sophisticated form of puzzle-solving where the letters are the pieces you need to figure out.

Basic algebra typically involves:

1. **Variables:** Symbols representing unknown numbers (e.g., x , y , a).
2. **Constants:** Numbers that have a fixed value (e.g., 5, -2, 100).
3. **Expressions:** Combinations of variables, constants, and mathematical operations (+, -, *, /) (e.g., $2x + 5$).
4. **Equations:** A statement that two expressions are equal, connected by an equals sign (=) (e.g., $2x + 5 = 15$). The goal is to find the value of the variable that makes the equation true.

Mastering basic algebra is crucial for further mathematical studies, science, engineering, economics, and even certain aspects of computer science. It's the foundation upon which more complex concepts are built.

The Cornerstone of Algebra: Solving Linear Equations

Linear equations are the most common type of equation you'll encounter in basic algebra. They are called "linear" because when graphed, they form a straight line. The primary goal when solving a linear equation is to isolate the variable on one side of the equals sign.

Problem Type 1: One-Step Equations

These are the simplest linear equations, requiring only one operation to solve for the variable. The key is to perform the *inverse operation* to both sides of the equation to maintain balance.

Example 1.1: Addition Equation

Problem: $x + 7 = 12$

Solution: To isolate 'x', we need to undo the addition of 7. The inverse operation of addition is subtraction. So, we subtract 7 from both sides of the equation:

$$x + 7 - 7 = 12 - 7$$

$$x = 5$$

Check: Substitute $x = 5$ back into the original equation: $5 + 7 = 12$. It's true!

Example 1.2: Subtraction Equation

Problem: $y - 3 = 9$

Solution: To isolate 'y', we need to undo the subtraction of 3. The inverse operation of subtraction is addition. So, we add 3 to both sides:

$$y - 3 + 3 = 9 + 3$$

$$y = 12$$

Check: $12 - 3 = 9$. Correct!

Example 1.3: Multiplication Equation

Problem: $4a = 20$

Solution: Here, 'a' is multiplied by 4. The inverse operation of multiplication is division. We divide both sides by 4:

$$4a / 4 = 20 / 4$$

$$a = 5$$

Check: $4 * 5 = 20$. Works perfectly!

Example 1.4: Division Equation

Problem: $b / 2 = 6$

Solution: 'b' is divided by 2. The inverse operation of division is multiplication. We multiply both sides by 2:

$$(b / 2) * 2 = 6 * 2$$

$$b = 12$$

Check: $12 / 2 = 6$. You've got it!

Problem Type 2: Two-Step Equations

These equations involve two operations that need to be undone to isolate the variable. The general strategy is to undo addition/subtraction first, then undo multiplication/division. This order is important to simplify the equation systematically.

Example 2.1: Combining Operations

Problem: $3m + 5 = 20$

Solution:

1. First, undo the addition of 5 by subtracting 5 from both sides:

$$3m + 5 - 5 = 20 - 5$$

$$3m = 15$$

2. Next, undo the multiplication by 3 by dividing both sides by 3:

$$3m / 3 = 15 / 3$$

$$m = 5$$

Check: $3 * 5 + 5 = 15 + 5 = 20$. Nailed it!

Example 2.2: More Complex Two-Step

Problem: $(n / 4) - 2 = 8$

Solution:

1. First, undo the subtraction of 2 by adding 2 to both sides:

$$(n / 4) - 2 + 2 = 8 + 2$$

$$n / 4 = 10$$

2. Next, undo the division by 4 by multiplying both sides by 4:

$$(n / 4) * 4 = 10 * 4$$

$$n = 40$$

Check: $(40 / 4) - 2 = 10 - 2 = 8$. Excellent!

Problem Type 3: Equations with Variables on Both Sides

When variables appear on both the left and right sides of the equation, our goal is to gather all the variable terms on one side and all the constant terms on the other. This usually involves a few more steps but follows the same principles of inverse operations.

Example 3.1: Bringing Variables Together

Problem: $5p + 3 = 2p + 15$

Solution:

1. We want to get all the 'p' terms on one side. Let's move the '2p' from the right to the left by subtracting 2p from both sides:

$$5p + 3 - 2p = 2p + 15 - 2p$$

$$3p + 3 = 15$$

2. Now we have a two-step equation! Subtract 3 from both sides to isolate the 'p' term:

$$3p + 3 - 3 = 15 - 3$$

$$3p = 12$$

3. Finally, divide both sides by 3 to solve for 'p':

$$3p / 3 = 12 / 3$$

$$p = 4$$

Check: Left side: $5(4) + 3 = 20 + 3 = 23$. Right side: $2(4) + 15 = 8 + 15 = 23$. They match!

Beyond Linear Equations: Introducing Inequalities

While equations state that two expressions are equal, inequalities express a relationship of "greater than," "less than," "greater than or equal to," or "less than or equal to." Solving inequalities is very similar to solving equations, with one crucial difference:

Rule: When you multiply or divide both sides of an inequality by a *negative* number, you must *reverse* the inequality symbol.

Example 4.1: Simple Inequality

Problem: $2x - 1 < 7$

Solution:

1. Add 1 to both sides:

$$2x - 1 + 1 < 7 + 1$$

$$2x < 8$$

2. Divide both sides by 2 (a positive number, so no change in

symbol):

$$2x / 2 < 8 / 2$$

$$x < 4$$

This means any number less than 4 will satisfy the original inequality.

Example 4.2: Inequality Requiring Symbol Reversal

Problem: $-3y + 5 \geq 11$

Solution:

1. Subtract 5 from both sides:

$$-3y + 5 - 5 \geq 11 - 5$$

$$-3y \geq 6$$

2. Divide both sides by -3. Since we are dividing by a negative number, we MUST reverse the inequality symbol:

$$-3y / -3 \leq 6 / -3$$

$$y \leq -2$$

This means any number less than or equal to -2 will satisfy the inequality.

Putting Algebra to Work: Word Problems

The true power of algebra lies in its ability to model and solve real-world problems. Word problems can seem intimidating, but the process is simply about translating the words into mathematical equations. Here's a systematic approach:

1. **Read Carefully:** Understand the problem completely. What is being asked?
2. **Identify the Unknown:** What quantity are you trying to find? Assign a variable (like 'x') to represent it.
3. **Translate to an Equation:** Break down the sentences and convert the relationships between numbers and the unknown into a mathematical equation. Look for keywords that indicate operations (e.g., "sum" for addition, "difference" for subtraction, "product" for multiplication, "quotient" for division).
4. **Solve the Equation:** Use the techniques you've learned to find the value of the variable.
5. **Check Your Answer:** Does the answer make sense in the context of the word problem?

Example 5.1: A Simple Age Problem

Problem: Sarah is 5 years older than her brother Tom. Together, their ages add up to 35. How old is each of them?

Solution:

1. **Unknowns:** Sarah's age and Tom's age.

2. **Variables:** Let 't' represent Tom's age. Since Sarah is 5 years older, Sarah's age can be represented as 't + 5'.
3. **Equation:** "Together, their ages add up to 35" translates to:

$$t + (t + 5) = 35$$

4. **Solve:**

$$2t + 5 = 35$$

$$2t = 30$$

$$t = 15 \text{ (Tom's age)}$$

5. **Find Sarah's age:** Sarah's age = $t + 5 = 15 + 5 = 20$.
6. **Check:** Tom is 15, Sarah is 20. Sarah is 5 years older than Tom ($20 - 15 = 5$). Their ages add up to 35 ($15 + 20 = 35$). The answer is correct!

Example 5.2: A Rate Problem

Problem: A car travels at a speed of 60 miles per hour. How long will it take to travel 240 miles?

Solution:

1. **Unknown:** Time.
2. **Variable:** Let 't' represent the time in hours.
3. **Equation:** We use the formula: Distance = Speed $\times$ Time.

$$240 \text{ miles} = 60 \text{ mph} \times t$$

4. **Solve:**

$$240 = 60t$$

$$240 / 60 = t$$

$$t = 4 \text{ hours}$$

5. **Check:** In 4 hours, at 60 mph, the car travels $60 * 4 = 240$ miles. Correct!

The ability to manipulate variables, solve for unknowns, and understand proportionality forms the bedrock of logical reasoning and problem-solving. This article aims to equip you with the knowledge and confidence to navigate the world of elementary algebra, from simple linear equations to more complex word problems.

What is Basic Algebra? The Core Concepts

Basic algebra, also known as elementary algebra, introduces the concept of variables – symbols (usually letters like 'x', 'y', or 'a') that represent unknown quantities. The primary goal is

to find the value of these variables that makes an equation true. This involves understanding:

1. **Variables:** The unknowns we are trying to solve for.
2. **Constants:** Fixed numerical values.
3. **Expressions:** Combinations of variables, constants, and mathematical operations (addition, subtraction, multiplication, division). For example, $2x + 5$ is an algebraic expression.
4. **Equations:** A statement that two expressions are equal, connected by an equals sign ($=$). For example, $2x + 5 = 11$.
5. **Solving Equations:** The process of isolating the variable on one side of the equation to determine its value.

The fundamental principle guiding the solution of any equation is to maintain balance. Whatever operation you perform on one side of the equals sign, you must perform the exact same operation on the other side to keep the equation true. This is the cornerstone of algebraic manipulation.

Types of Basic Algebra Problems and Their Solutions

Let's break down the most common types of basic algebra problems and how to solve them. We'll move from the simplest to slightly more involved scenarios.

1. Solving One-Step Linear Equations

These are the simplest equations, requiring only one operation to isolate the variable. They typically involve

addition, subtraction, multiplication, or division.

Example 1: Addition

Problem: $x + 7 = 15$

Solution: To isolate 'x', we need to undo the addition of 7. We do this by subtracting 7 from both sides of the equation:

$$x + 7 - 7 = 15 - 7$$

$$x = 8$$

Verification: Substitute $x = 8$ back into the original equation:
 $8 + 7 = 15$. This is true.

Example 2: Subtraction

Problem: $y - 3 = 9$

Solution: To isolate 'y', we add 3 to both sides:

$$y - 3 + 3 = 9 + 3$$

$$y = 12$$

Verification: $12 - 3 = 9$. True.

Example 3: Multiplication

Problem: $4a = 20$

Solution: To isolate 'a', we undo the multiplication by 4. We do this by dividing both sides by 4:

$$4a / 4 = 20 / 4$$

$$a = 5$$

Verification: $4 * 5 = 20$. True.

Example 4: Division

Problem: $b / 5 = 6$

Solution: To isolate 'b', we undo the division by 5. We do this by multiplying both sides by 5:

$$(b / 5) * 5 = 6 * 5$$

$$b = 30$$

Verification: $30 / 5 = 6$. True.

2. Solving Two-Step Linear Equations

These equations require two operations to isolate the variable. The key is to follow the order of operations in reverse (often referred to as SADMEP - inverse of PEMDAS/BODMAS). Generally, you'll deal with addition/subtraction first, then multiplication/division.

Example 5: A Typical Two-Step Equation

Problem: $3x + 5 = 17$

Solution:

1. **Step 1: Undo addition/subtraction.** Subtract 5 from both sides:

$$3x + 5 - 5 = 17 - 5$$

$$3x = 12$$

2. **Step 2: Undo multiplication/division.** Divide both sides

by 3:

$$3x / 3 = 12 / 3$$

$$x = 4$$

Verification: $3 * 4 + 5 = 12 + 5 = 17$. True.

Example 6: Another Two-Step Equation

Problem: $(m / 2) - 4 = 3$

Solution:

1. **Step 1: Undo addition/subtraction.** Add 4 to both sides:

$$(m / 2) - 4 + 4 = 3 + 4$$

$$m / 2 = 7$$

2. **Step 2: Undo multiplication/division.** Multiply both sides by 2:

$$(m / 2) * 2 = 7 * 2$$

$$m = 14$$

Verification: $(14 / 2) - 4 = 7 - 4 = 3$. True.

3. Solving Multi-Step Linear Equations (with variables on one side)

These problems might involve combining like terms or distributing before you can isolate the variable.

Understanding the distributive property is key here.

Example 7: Combining Like Terms

Problem: $5x - 2x + 8 = 14$

Solution:

1. **Step 1: Combine like terms.** On the left side, $5x$ and $-2x$ are like terms:

$$3x + 8 = 14$$

2. **Step 2: Solve the resulting two-step equation.** Subtract 8 from both sides:

$$3x + 8 - 8 = 14 - 8$$

$$3x = 6$$

3. **Step 3: Divide both sides by 3:**

$$3x / 3 = 6 / 3$$

$$x = 2$$

Verification: $5 * 2 - 2 * 2 + 8 = 10 - 4 + 8 = 6 + 8 = 14$.
True.

Example 8: Using the Distributive Property

Problem: $2(y + 3) = 10$

Solution:

1. **Step 1: Apply the distributive property.** Multiply 2 by both terms inside the parentheses:

$$2*y + 2*3 = 10$$

$$2y + 6 = 10$$

2. **Step 2: Solve the resulting two-step equation.** Subtract 6 from both sides:

$$2y + 6 - 6 = 10 - 6$$

$$2y = 4$$

3. **Step 3: Divide both sides by 2:**

$$2y / 2 = 4 / 2$$

$$y = 2$$

Verification: $2(2 + 3) = 2(5) = 10$. True.

4. Solving Linear Equations with Variables on Both Sides

These problems require an extra step: gathering all terms containing the variable on one side of the equation and all constant terms on the other.

Example 9: Variable on Both Sides

Problem: $5x - 3 = 2x + 9$

Solution:

1. **Step 1: Move all variable terms to one side.** Subtract $2x$ from both sides (to keep coefficients positive, if possible):

$$5x - 2x - 3 = 2x - 2x + 9$$

$$3x - 3 = 9$$

2. **Step 2: Move all constant terms to the other side.** Add 3 to both sides:

$$3x - 3 + 3 = 9 + 3$$

$$3x = 12$$

3. **Step 3: Solve for the variable.** Divide both sides by 3:

$$3x / 3 = 12 / 3$$

$$x = 4$$

Verification: Left side: $5 \cdot 4 - 3 = 20 - 3 = 17$. Right side: $2 \cdot 4 + 9 = 8 + 9 = 17$. Both sides equal 17.

5. Solving Basic Inequality Problems

Inequalities use symbols like $<$ (less than), $>$ (greater than), $\leq$ (less than or equal to), and $\geq$ (greater than or equal to). The rules for solving inequalities are similar to equations, with one crucial exception: when you multiply or divide both sides by a negative number, you must reverse the inequality sign.

Example 10: Simple Inequality

Problem: $2x + 1 < 7$

Solution:

1. **Step 1: Subtract 1 from both sides:**

$$2x + 1 - 1 < 7 - 1$$

$$2x < 6$$

2. **Step 2: Divide both sides by 2:**

$$2x / 2 < 6 / 2$$

$$x < 3$$

Interpretation: Any value of x that is less than 3 will satisfy this inequality.

Example 11: Inequality with a Negative Multiplier

Problem: $-3y + 5 \geq 11$

Solution:

1. **Step 1: Subtract 5 from both sides:**

$$-3y + 5 - 5 \geq 11 - 5$$

$$-3y \geq 6$$

2. **Step 2: Divide both sides by -3. Remember to reverse the inequality sign:**

$$-3y / -3 \leq 6 / -3$$

$$y \leq -2$$

Interpretation: Any value of y that is less than or equal to -2 will satisfy this inequality.

Word Problems in Basic Algebra

Word problems are where the abstract concepts of algebra

meet real-world scenarios. The key to solving them is to translate the words into mathematical equations.

Strategy for Solving Word Problems:

1. **Read Carefully:** Understand the problem completely.
2. **Identify the Unknown:** What are you trying to find?
Assign a variable to this unknown.
3. **Identify the Knowns:** What information is given in the problem?
4. **Translate into an Equation:** Use the variable and the given information to write an algebraic equation or inequality. Look for keywords like "is," "equals," "sum," "difference," "product," "quotient," "more than," "less than," etc.
5. **Solve the Equation:** Use the methods discussed above.
6. **Check Your Answer:** Does the answer make sense in the context of the original word problem?

Example 12: Age Problem

3. **Knowns:** Sum of their ages is 31.
4. **Equation:** Tom's age + Sarah's age = 31. So, $T + (T + 5) = 31$.

5. **Solve:**

$$T + T + 5 = 31$$

$$2T + 5 = 31$$

$$2T = 31 - 5$$

$$2T = 26$$

$$T = 13$$

6. **Find both ages:** Tom's age (T) is 13. Sarah's age (T + 5) is $13 + 5 = 18$.

7. **Check:** $13 + 18 = 31$. Sarah (18) is 5 years older than Tom (13). The answer makes sense.

Example 13: Distance, Rate, and Time

Problem: A train travels at a speed of 60 miles per hour. How long will it take to travel 180 miles?

Solution:

1. **Unknown:** Time.

2. **Variable:** Let 't' represent the time in hours.

3. **Knowns:** Rate (speed) = 60 mph, Distance = 180 miles.

4. **Equation:** The formula for distance is Distance = Rate $\times$ Time ($D = R * t$). So, $180 = 60 * t$.

5. **Solve:**

$$180 = 60t$$

$$180 / 60 = t$$

$$t = 3$$

6. **Answer:** It will take 3 hours.
7. **Check:** $60 \text{ mph} \times 3 \text{ hours} = 180 \text{ miles}$. Correct.

Questions & Answers About basic algebra problems and solutions

No	Question	Answer
1	What's the quickest way to solve for 'x' in a simple equation like $2x + 5 = 15$?	To solve for 'x', isolate it by performing inverse operations. First, subtract 5 from both sides ($2x = 10$), then divide both sides by 2 ($x = 5$). Always do the same operation to both sides to maintain equality.

2	I keep messing up with negative numbers in algebra. What's the golden rule for combining them?	The key is to think of it like a number line. Adding a negative is moving left, subtracting a negative is moving right. For multiplication/division: same signs (both positive or both negative) result in a positive answer; different signs result in a negative answer.
3	What's the difference between an expression and an equation in algebra?	An expression is a combination of numbers, variables, and operations (like $3x + 7$) and doesn't have an equals sign. An equation has an equals sign and states that two expressions are equal (like $3x + 7 = 13$).
4	How do I simplify an algebraic expression with multiple terms, like $4a + 7b - 2a + 3b$?	Combine 'like terms' - terms with the same variable raised to the same power. In this case, combine the 'a' terms ($4a - 2a = 2a$) and the 'b' terms ($7b + 3b = 10b$). The simplified expression is $2a + 10b$.
5	When dealing with parentheses in algebra, what's the first step I should always take?	Usually, the first step is to 'distribute' any number or variable outside the parentheses to each term inside. For example, in $3(x + 2)$, you'd multiply 3 by x and 3 by 2 to get $3x + 6$.
6	What does it mean to 'solve for the variable' in an algebraic problem?	It means finding the specific numerical value of the variable (like 'x' or 'y') that makes the equation true. You're essentially finding the number that fits into the equation perfectly.
7	I'm confused about what a coefficient is. Can you explain it simply?	A coefficient is the number that is multiplied by a variable. In the term $5x$, the coefficient is 5. It tells you how many of that variable you have.

8	What's the fundamental principle for solving any algebraic equation?	The core principle is balance. Whatever operation you perform on one side of the equation, you must perform the exact same operation on the other side. This keeps the equation true.
9	How do I handle word problems that involve basic algebra? Where do I even start?	Read the problem carefully and identify what you need to find (this will be your variable). Assign a variable (like 'x') to represent it. Translate the words into an algebraic equation by looking for keywords that indicate operations (e.g., 'more than' means addition, 'times' means multiplication). Then, solve the equation.
